Tilburg, June 1988.

The paper was written at Tilburg University during a research stay supported by the Netherlands Organization for Scientific Research (NWO). I greatly benefited from discussions with Mark F.J. Steel and from his comments on the first draft.

## 1. Introduction

The paper continues the Bayesian analysis of nonlinear regression models, that is models of known functional form (nonlinear in parameters) and with an additive error term. In this area of Bayesian research, Zellner (1971, §6.2), Sankar (1970), H. Tsurumi and Y. Tsurumi (1976), Harkema and Schim van der Loeff (1977) focus their attention on the estimation of CES production functions parameters; Box and Tiao (1973, p. 436) present an approximate Bayesian approach based on linearization; Eaves (1983) considers a reference prior - in the sense of Bernardo (1979) - and gives an illustration of discrepancies between exact and approximate posterior densities; Broemeling (1985, p. 104-116) presents general formulae of posterior and predictive densities and points at some easy special cases and at useful approximations.

In Osiewalski (1987) and Osiewalski and Goryl (1986, 1988) - all in Polish - posterior densities and moments for some specific nonlinear models (logistic growth function, Törnquist-type Engel curves) under Jeffreys' (or reference) priors are derived.

This paper generalizes the approach adopted previously for the CES functions and deals with Bayesian estimation and prediction for those nonlinear regression models which are linear in some parameters (say,  $\beta_1, \dots, \beta_k$ ) given values of the remaining parameters (say,  $\eta_1, \dots, \eta_q$ ). This class of nonlinear regression models is worth considering since the exact Bayesian analysis with an appropriately chosen prior requires only  $q$ - or  $(q+1)$ -dimensional numerical integrations, irrespective of  $k$ .

The plan of the paper is as follows: some introductory remarks on Bayesian nonlinear regression are given in Section 2; in Section 3 the class of "partly linear" nonlinear models is introduced; posterior and predictive densities and moments under the assumption of improper uniform prior of  $\beta = (\beta_1, \dots, \beta_k)'$  are derived in Section 4, where the correspondence of this prior with Jeffreys' prior is discussed as well. The use of a finite mixture of normal or  $t$  distributions as a prior of  $\beta$  is considered in Section 5 and corresponding posterior and predictive densities are derived

there. Concluding remarks and comments on applications are given in Section 6.

### 1.1. Notation and main identities

Throughout the paper  $p(\cdot)$  denotes a probability density function (PDF) with special notation for PDF's of gamma, normal and t distributions. For  $x \in R^k$ ,  $p_N^k(x|c, W)$  denotes a k-variate normal PDF with a mean vector  $c$  and a covariance matrix  $W$ , and  $p_S^k(x|r, c, T)$  denotes a k-variate Student t PDF with  $r$  degrees of freedom,  $\sigma$  noncentrality vector  $c$  and a precision matrix  $T$ .

For  $w \in R_+$ ,

$$p_{\gamma}(w|a, b) = \frac{b^a}{\Gamma(a)} w^{a-1} \exp(-bw),$$

that is a gamma PDF with parameters  $a > 0$ ,  $b > 0$ . The following identities are used:

$$\int_{R^k} p_N^m(y|Qx + a, S) p_N^k(x|b, c) dx = p_N^m(y|Qb + a, S + QQQ'), \quad (1.1)$$

$$\begin{aligned} p_N^k(x|c, \frac{1}{w} A^{-1}) p_{\gamma}(w|\frac{a}{2}, \frac{b}{2}) &= \\ &= p_{\gamma}(w|\frac{a+k}{2}, \frac{1}{2}[b + (x-c)' A(x-c)]) p_S^k(x|a, c, \frac{a}{b} A), \end{aligned} \quad (1.2)$$

and

$$\int_0^\infty p_N^k(x|c, \frac{1}{w} A^{-1}) p_{\gamma}(w|\frac{a}{2}, \frac{b}{2}) dw = p_S^k(x|a, c, \frac{a}{b} A), \quad (1.3)$$

which is an immediate consequence of (1.2).

## 2. A Bayesian approach to nonlinear regression models

Let us consider the nonlinear regression model

$$y_t = h(z_t; \theta) + u_t, \quad u_t \sim \text{iin}(0, \sigma^2) \quad (2.1)$$

where  $z_t$  is a  $r \times 1$  vector of independent variables,  $\theta$  is a  $K \times 1$  unknown parameter vector,  $z_t \in R^r$ ,  $\theta \in \Theta$  ( $\Theta$  is a full-dimensional subset of  $R^K$ ),  $h: R^r \times \Theta \rightarrow R$  is a known function;  $\sigma^2$  is an unknown nuisance parameter. We assume that  $h(z_t; \theta)$  is not linear in  $\theta$  (given  $z_t$ ) and that this function (as a function of  $\theta$  given  $z_t$ ) is sufficiently well-behaved to insure the existence of certain derivatives and integrals which appear in Bayesian analysis. We treat  $z_t$  as a known nonstochastic vector<sup>1)</sup> and assume that (given  $z_1, \dots, z_n, z_{n+1}, \dots, z_{n+m}$ ) one observes  $y = (y_1, \dots, y_n)'$  and one has to make inferences about  $\theta$  and to forecast  $\tilde{y} = (\tilde{y}_1, \dots, \tilde{y}_m)' = (y_{n+1}, \dots, y_{n+m})'$ .

Let

$$Z = (z_1 \ z_2 \ \dots \ z_n)', \quad \tilde{Z} = (z_{n+1} \ \dots \ z_{n+m})', \quad \omega = \sigma^{-2}$$

and let  $p(y, \tilde{y} | Z, \tilde{Z}, \theta, \omega)$  denote the joint density of current and future observations given the values of independent variables and parameters. In our i.i.d. case

$$p(y, \tilde{y} | Z, \tilde{Z}, \theta, \omega) = p(y | Z, \theta, \omega) p(\tilde{y} | \tilde{Z}, \theta, \omega)$$

---

1) Of course, this assumption can be relaxed. If  $z_t$  is weakly exogenous for  $(\theta, \sigma^2)$  over the sample period and parameters of the marginal process generating  $z_t$  are prior independent of  $(\theta, \sigma^2)$ , then all the posterior results (obtained in Sections 4, 5) hold. If, additionally,  $z_t$  is strongly exogenous for  $(\theta, \sigma^2)$  over the forecast period, then all the predictive results hold. For definitions of weak and strong exogeneity see Engle, Hendry and Richard (1983).

and all the densities are densities of appropriate normal distributions:  $(n+m)$ -,  $n$ - and  $m$ -dimensional, respectively.

In the Bayesian approach, all inferences about  $\theta$  are based on the marginal posterior PDF  $p(\theta|y, Z)$  obtained from the joint posterior PDF

$$p(\theta, \omega|y, Z) \propto p(\theta, \omega) \cdot p(y|Z, \theta, \omega)$$

where  $p(\theta, \omega)$  is the prior PDF. Bayesian prediction of  $\tilde{y}$  is based on the predictive PDF

$$p(\tilde{y}|y, Z, \tilde{Z}) = \int_{\Theta} \int_0^{\infty} p(\tilde{y}|\tilde{Z}, \theta, \omega) p(\theta, \omega|y, Z) d\omega d\theta; \quad (2.2)$$

see Zellner (1971, ch. 2). When the prior density of  $\theta$  and  $\omega$  is composed of a gamma PDF on  $\omega$  and an independent prior on  $\theta$ :

$$p(\theta, \omega) \propto p(\theta) p_{\gamma}(\omega|\frac{e}{2}, \frac{f}{2}), \quad \theta \in \Theta, \quad \omega \in R_+,$$

then - rewriting Broemeling's formulae (3.81) and (3.77)-(3.80) in our notation - we have, using the natural-conjugate properties of gamma densities for our model,

$$p(\theta|y, Z) \propto p(\theta) \left\{ f + \sum_{t=1}^n [y_t - h(z_t; \theta)]^2 \right\}^{-\frac{1}{2}(e+n)} \quad (2.3)$$

as the unnormalized posterior PDF of  $\theta$  and

$$p(\tilde{y}_j|y, Z, z_{n+j}) = \int_{\Theta} p_s^1 \left[ \tilde{y}_j | e+n, h(z_{n+j}; \theta), \frac{e+n}{f + \sum_{t=1}^n [y_t - h(z_t; \theta)]^2} \right] \times \\ \times p(\theta|y, Z) d\theta \quad (2.4)$$

as the (marginal) univariate predictive PDF. In this general formulation of the model, the posterior and predictive PDF's are not tractable and (generally) require  $K$ -dimensional numerical integrations in order to obtain the normalizing constant, moments, univariate posterior densities

etc. Broemeling (1985, p. 107) writes: "One may sum up the Bayesian analysis of nonlinear regression, when  $\theta$  is scalar, by saying a complete analysis is possible (...); however, if  $\theta$  is of dimension greater than or equal to two, a Bayesian analysis becomes more difficult" and when  $\theta$  is of dimension 3 or greater "the numerical integration problems become impractical". On the other hand, Broemeling (1985, p. 108) realizes that "there are some special cases, where an exact and complete Bayesian analysis is possible" and gives as an example

$$h(z_t, \theta) = \theta_2 h_1(z_t, \theta_1), \theta_1 \in R, \theta_2 \in R.$$

Let us note, however, that in econometric literature much more complicated functional forms of  $h$  were successfully analyzed, namely the forms obtained by taking logarithms of both sides of different CES production functions with multiplicative lognormal errors; see Sankar (1970), H. Tsurumi and Y. Tsurumi (1976).

Bayesian estimation of 5 or more unknown parameters of CES functions required bivariate or trivariate numerical integration; great analytical simplifications were possible because the models were linear in some parameters and uniform priors for these parameters led to "partly tractable" posteriors. The obvious conclusion is that the Bayesian analysis of a given nonlinear model should exploit linearities in order to become "more practical". The aim of this paper is to provide general formulae of posterior and predictive densities and moments for the case of a nonlinear model which is linear in some parameters. The approach, used previously for some specific cases, is generalized into three main directions:

- 1) a general - not specific - form of "partly linear" model is considered,
- 2) not only uniform improper but also some proper informative priors are allowed,
- 3) not only posterior, but also predictive PDF's are derived.

### 3. Partly linear regression models

Let us restrict our considerations to nonlinear models of the following functional form:

$$h(z_t, \theta) = x_0(z_t, \eta) + \beta_1 x_1(z_t, \eta) + \dots + \beta_k x_k(z_t, \eta), \quad (3.1)$$

where  $\theta = (\beta', \eta')'$ ,  $\beta = (\beta_1, \dots, \beta_k)' \in \mathbb{R}^k$   
 $\eta = (\eta_1, \dots, \eta_q)' \in H \subset \mathbb{R}^q$ ,  $k + q = K$ ,

$x_i(z_t, \eta)$  for  $i = 0, 1, \dots, k$  are known functions (sufficiently well-behaved), and  $H$  is a (full-dimensional) set of admissible values of  $\eta$ . That is, we are interested in models where it is possible to divide a parameter vector ( $\theta$ ) into two separate subvectors ( $\beta$  and  $\eta$ ) in such a way that - given  $\eta$  - the model is linear with respect to  $\beta$ . For  $n$  observations ( $t = 1, \dots, n$ ) and  $m$  values to be predicted ( $t = n + 1, \dots, n + m$ ) we have

$$\begin{bmatrix} y \\ \tilde{y} \end{bmatrix} = \begin{bmatrix} w_\eta \\ \tilde{w}_\eta \end{bmatrix} + \begin{bmatrix} X_\eta \\ \tilde{X}_\eta \end{bmatrix} \beta + \begin{bmatrix} u \\ \tilde{u} \end{bmatrix},$$

$$\begin{bmatrix} u \\ \tilde{u} \end{bmatrix} \sim N(0, \frac{1}{\omega} I_{n+m}),$$

where

$$w_\eta = \begin{bmatrix} x_0(z_1, \eta) \\ \cdot \\ \cdot \\ \cdot \\ x_0(z_n, \eta) \end{bmatrix}, \quad X_\eta = \begin{bmatrix} x_1(z_1, \eta) & \cdot & \cdot & \cdot & x_k(z_1, \eta) \\ \cdot & & & & \cdot \\ \cdot & & & & \cdot \\ \cdot & & & & \cdot \\ x_1(z_n, \eta) & \cdot & \cdot & \cdot & x_k(z_n, \eta) \end{bmatrix},$$

$$\tilde{w}_\eta = \begin{bmatrix} x_0(z_{n+1}, \eta) \\ \cdot \\ \cdot \\ \cdot \\ x_0(z_{n+m}, \eta) \end{bmatrix}, \quad \tilde{X}_\eta = \begin{bmatrix} x_1(z_{n+1}, \eta) & \cdot & \cdot & \cdot & x_k(z_{n+1}, \eta) \\ \cdot & & & & \cdot \\ \cdot & & & & \cdot \\ \cdot & & & & \cdot \\ x_1(z_{n+m}, \eta) & \cdot & \cdot & \cdot & x_k(z_{n+m}, \eta) \end{bmatrix},$$

$$u = (u_1, \dots, u_n)', \quad \tilde{u} = (u_{n+1}, \dots, u_{n+m})'.$$

The data distribution and the distribution of future values are independent normal distributions:

$$p(y, \tilde{y} | Z, \tilde{Z}, \beta, \eta, \omega) = p(y | Z, \beta, \eta, \omega) p(\tilde{y} | \tilde{Z}, \beta, \eta, \omega),$$

$$p(y | Z, \beta, \eta, \omega) = p_N^n(y | X_\eta \beta + w_\eta, \omega^{-1} I_n),$$

$$p(\tilde{y} | \tilde{Z}, \beta, \eta, \omega) = p_N^m(\tilde{y} | \tilde{X}_\eta \beta + \tilde{w}_\eta, \omega^{-1} I_m).$$

Let us assume that the  $n \times k$  matrix  $X_\eta$  is of full column rank ( $k$ ) for every  $\eta \in H$ . Now  $X_\eta' X_\eta$  is a nonsingular  $k \times k$  matrix and we can define

$$b_\eta = (X_\eta' X_\eta)^{-1} X_\eta' (y - w_\eta), \quad s_\eta = (y - w_\eta - X_\eta b_\eta)' (y - w_\eta - X_\eta b_\eta).$$

The following equality holds:

$$(y - w_\eta - X_\eta \beta)' (y - w_\eta - X_\eta \beta) = s_\eta + (\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta),$$

which enables us to write the data density (or the likelihood function) in the more convenient form

$$p(y | Z, \beta, \eta, \omega) = (2\pi)^{-\frac{n}{2}} \omega^{\frac{n}{2}} \exp \left\{ -\frac{\omega}{2} [s_\eta + (\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta)] \right\}. \quad (3.2)$$

Except for the dependence of  $X_\eta$ ,  $b_\eta$ ,  $s_\eta$  on unknown  $\eta$ , the likelihood function looks like its counterpart for the usual linear model. In order to take advantage of this similarity, an appropriate class of priors should

be considered. In the linear case ( $\eta$  known) Jeffreys' improper prior and proper natural conjugate normal-gamma priors of  $(\beta, \omega)$  give completely analytical posterior and predictive results, and independent priors of the form: Student t (or normal for  $\beta$  and gamma for  $\omega$ ) lead to univariate numerical integrations only, so these facts suggest the classes of priors worth considering in our nonlinear - partly linear case. We assume here that  $\theta = (\beta' \eta)'$  and  $\omega$  are independent a priori:

$$p(\beta, \eta, \omega) = p(\beta, \eta) p(\omega) \quad (3.3)$$

and

$$p(\omega) \propto \omega^{\frac{e}{2}-1} \exp\left(-\frac{f}{2} \cdot \omega\right);$$

$e = f = 0$  correspond to the improper prior  $p(\omega) \propto \omega^{-1}$ , if  $e > 0$  and  $f > 0$  then  $p(\omega) = p_{\chi}(\omega | \frac{e}{2}, \frac{f}{2})$ .

We will consider three types of priors of  $(\beta, \eta)$ :

$$p_1(\beta, \eta) \propto g(\eta),$$

$$p_i(\beta, \eta) = p_i(\beta | \eta) p(\eta), \quad i = 2, 3.$$

For  $i = 2, 3$ ,  $p(\eta)$  is some marginal prior density of  $\eta$  and  $p_i(\beta | \eta)$  are informative conditional priors of  $\beta$  (given  $\eta$ ) which are finite mixtures of normal ( $i=2$ ) or t ( $i=3$ ) densities.

In the case of  $p_1(\beta, \eta)$ ,  $g(\eta)$  need not be the marginal prior since we do not impose the assumption of prior independence between  $\beta$  and  $\eta$ , but only between  $(\beta, \eta)$  and  $\omega$ . A clarifying example of this is given by Jeffreys' prior (4.2) in Subsection 4.2.

Of course, the assumption (3.3) will complicate the analysis in the cases of informative priors of  $\beta$ . Conditionally on  $\eta$ , the natural-conjugate framework would be more convenient. That is, we could assume that  $p(\beta, \omega | \eta)$  is a finite mixture of normal-gamma densities and that  $p(\eta)$  is any given PDF. Then, the similar lines of reasoning as in subsection 5.2 would lead

to analytical integrations with respect to  $\beta$  and  $\omega$ , and only  $q$ -dimensional numerical integration (with respect to  $\eta$ ) would be required. But, as in the linear case, the dependence between  $\beta$  and  $\omega$  in the natural-conjugate normal-gamma prior may cause some serious problems, e.g. it may require rather strong prior beliefs about  $\omega$  in order to achieve some preassumed prior moments of  $\beta$ . The assumption (3.3) enables to avoid such troubles at the expense of one more dimension in numerical integration. In particular, this assumption allows for expressing strong beliefs about  $\beta$  and the lack of opinion about  $\omega$  simultaneously.

#### 4. Bayesian analysis with an improper uniform prior density for $\beta$

##### 4.1. Posterior and predictive PDF's

For the likelihood function (3.2) and for the prior density

$$p_1(\beta, \eta, \omega) \propto g(\eta) \omega^{\frac{e}{2}-1} \exp\left(-\frac{f}{2} \cdot \omega\right),$$

$$\beta \in R^k, \eta \in H \subset R^q, \omega \in R_+,$$

we obtain the following joint posterior PDF:

$$p_1(\beta, \eta, \omega | y, Z) \propto g(\eta) (f + s_\eta)^{-\frac{e+n-k}{2}} |X'_\eta X_\eta|^{-\frac{1}{2}} p_Y\left[\omega \left| \frac{e+n-k}{2}, \frac{f+s_\eta}{2} \right.\right] \times$$

$$\times p_N^k\left[\beta | b_\eta, \frac{1}{\omega} (X'_\eta X_\eta)^{-1}\right].$$

Now the joint posterior PDF can easily be represented as a product of appropriate marginal and conditional PDF's:

$$p_1(\beta, \eta, \omega | y, Z) = p_1(\eta | y, Z) p_1(\omega | y, Z, \eta) p_1(\beta | y, Z, \eta, \omega),$$

where

$$p_1(\eta | y, Z) \propto g(\eta) |X'_\eta X_\eta|^{-\frac{1}{2}} (f + s_\eta)^{-\frac{e+n-k}{2}},$$

$$p_1(\omega | y, Z, \eta) = p_Y\left[\omega \left| \frac{e+n-k}{2}, \frac{f+s_\eta}{2} \right.\right],$$

$$p_1(\beta | y, Z, \eta, \omega) = p_N^k\left[\beta | b_\eta, \frac{1}{\omega} (X'_\eta X_\eta)^{-1}\right].$$

Since - according to (1.2) -

$$p_N^k\left[\beta | b_\eta, \frac{1}{\omega} (X'_\eta X_\eta)^{-1}\right] p_Y\left[\omega \left| \frac{e+n-k}{2}, \frac{f+s_\eta}{2} \right.\right] =$$

$$= p_Y\left[\omega \middle| \frac{e+n}{2}, \frac{1}{2}[f + s_\eta + (\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta)]\right] p_S^k\left[\beta \middle| e+n-k, b_\eta, \frac{e+n-k}{f+s_\eta} X_\eta' X_\eta\right],$$

then the joint posterior PDF can be written equivalently as

$$p_1(\beta, \eta, \omega | y, Z) = p_1(\eta | y, Z) p_1(\beta | y, Z, \eta) p_1(\omega | y, Z, \beta, \eta),$$

where

$$p_1(\beta | y, Z, \eta) = p_S^k\left[\beta \middle| \bar{e}, b_\eta, \frac{\bar{e}}{f + s_\eta} X_\eta' X_\eta\right],$$

$$p_1(\omega | y, Z, \beta, \eta) = p_Y\left[\omega \middle| \frac{e + n}{2}, \frac{d}{2}\right],$$

and

$$\bar{e} = e + n - k, \quad d = f + s_\eta + (\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta).$$

For inferences about  $\eta$ , the marginal posterior PDF  $p_1(\eta | y, Z)$  should be used. This PDF is - in general - intractable and numerical integrations will usually be required to calculate a normalizing constant, moments and univariate marginal densities. For inferences about  $\beta$ , the marginal posterior PDF

$$p_1(\beta | y, Z) = \int_H p_1(\eta | y, Z) p_1(\beta | y, Z, \eta) d\eta$$

is appropriate. Since the conditional posterior PDF,  $p_1(\beta | y, Z, \eta)$ , is in Student t form, we have analytical formulae for conditional posterior moments and also for univariate PDF's  $p_1(\beta_i | y, Z, \eta)$ ,  $i = 1, \dots, k$ , which are of univariate Student t form.

Now the marginal posterior moments and densities can be calculated as

$$E_1(\beta | y, Z) = \int_H p_1(\eta | y, Z) b_\eta d\eta,$$

$$E_1(\beta\beta' | y, Z) = \int_H p_1(\eta | y, Z) \left[ \frac{f + s_\eta}{\bar{e} - 2} (X'_\eta X_\eta)^{-1} + b_\eta \cdot b'_\eta \right] d\eta,$$

$$p_1(\beta_1 | y, Z) = \int_H p_1(\eta | y, Z) p_1(\beta_1 | y, Z, \eta) d\eta.$$

For the calculation of mixed moments one can use the formula

$$E_1(\beta \cdot \eta' | y, Z) = \int_H p_1(\eta | y, Z) b_\eta \cdot \eta' d\eta.$$

In this paper  $\omega$  is treated as a nuisance parameter, but if some inferences about  $\omega$  are necessary then the marginal posterior PDF

$$p_1(\omega | y, Z) = \int_H p_1(\eta | y, Z) p_1(\omega | y, Z, \eta) d\eta$$

is appropriate and the known properties of  $p_1(\omega | y, Z, \eta) = p_\gamma\left(\omega | \frac{\bar{e}}{2}, \frac{f + s_\eta}{2}\right)$  can be used.

In order to derive the predictive PDF  $p_1(\tilde{y} | y, Z, \tilde{Z})$  according to (2.2), let us notice that in our case we can write

$$\begin{aligned} p_1(\tilde{y} | y, Z, \tilde{Z}) &= \int_H \int_0^\infty \int_{R^k} p(\tilde{y} | \tilde{Z}, \beta, \eta, \omega) p_1(\beta | y, Z, \eta, \omega) d\beta \times \\ &\times p_1(\omega | y, Z, \eta) d\omega p_1(\eta | y, Z) d\eta. \end{aligned}$$

Since the first and second densities after the integral signs are normal and the third density is gamma, then by successive analytical integrations based on (1.1) and (1.3) one obtains

$$\begin{aligned} p_1(\tilde{y} | y, Z, \tilde{Z}) &= \int_H p_s^m \left[ \tilde{y} | \bar{e}, \tilde{w}_\eta + \tilde{X}_\eta b_\eta, \frac{\bar{e}}{f + s_\eta} \left[ I_m + \tilde{X}_\eta (X'_\eta X_\eta)^{-1} \tilde{X}'_\eta \right]^{-1} \right] \times \\ &\times p_1(\eta | y, Z) d\eta. \end{aligned}$$

Moments and univariate densities of the predictive distribution can be calculated in the similar way as in the case of marginal posterior distribution of  $\beta$ . It means that, in the case of improper uniform prior of  $\beta$ , Bayesian estimation and prediction requires numerical integrations over

$H \subset R^q$ , irrespective of  $k$  (the dimension of  $\beta$ ). Of course,  $k$  plays a great role in calculating values of the integrand, since a  $k \times k$  matrix  $(X'X)_{\eta\eta}$  should be inverted for every  $\eta$ .

#### 4.2. Uniform prior of $\beta$ and Jeffreys' rule

Since the use of a prior from the class  $p_1(\beta, \eta, \omega)$  greatly simplifies the forms of posterior and predictive PDF's, let us comment on its uniformity in  $\beta$ . Intuitively, the uniform prior of  $\beta$  represents vague prior knowledge about  $\beta_1, \dots, \beta_k$  and indeed it was used as a noninformative prior in the case of CES function by H. Tsurumi and Y. Tsurumi (1976)<sup>2)</sup> and Sankar (1970).

But does this prior follow from any formal principle (as it does in the case of linear model, where the uniform prior can be justified in several ways)?

Let us return to the general model (2.1), that is

$$y_t = h(z_t, \theta) + u_t, \quad u_t \sim \text{iin}(0, \sigma^2),$$

and denote by  $D$  the  $n \times K$  matrix of first-order partial derivatives

$$d_{ti} = \frac{\partial h(z_t, \theta)}{\partial \theta_i} \quad (t = 1, \dots, n; i = 1, \dots, K).$$

We can write the information matrix (based on  $n$  observations) as

$$I(\theta, \sigma) = \left[ \begin{array}{c|c} \sigma^{-2} D'D & 0 \\ \hline 0 & 2n\sigma^{-2} \end{array} \right],$$

so an application of Jeffrey's rule separately for  $\theta$  and for  $\sigma$  gives

---

2) In fact, they assumed the uniform prior of all structural parameters.

$$p_J(\theta) \propto |D'D|^{\frac{1}{2}}, \quad p_J(\sigma) \propto \sigma^{-1},$$

and

$$p_J(\theta, \sigma) = p_J(\theta) p_J(\sigma) \propto \sigma^{-1} |D'D|^{\frac{1}{2}}$$

or, equivalently, in terms of  $\omega = \sigma^{-2}$

$$p_J(\theta, \omega) \propto \omega^{-1} |D'D|^{\frac{1}{2}}.$$

As Eaves (1983) pointed out,  $p_J(\theta, \sigma)$  is also a reference prior in the sense of Bernardo (1979), assuming that  $\theta$  is a parameter of interest and  $\sigma$  is a nuisance parameter.

For the partly linear model:

$$h(z_t; \theta) = h(z_t; \beta, \eta) = x_0(z_t, \eta) + \beta_1 x_1(z_t, \eta) + \dots + \beta_k x_k(z_t, \eta),$$

$D$  can be partitioned as  $D = [D_1 \ D_2]$ , where  $D_1$  is  $n \times k$  and consists of the following derivatives:

$$\frac{\partial h(z_t; \beta, \eta)}{\partial \beta_i} = x_i(z_t, \eta) \quad \begin{matrix} t = 1, \dots, n \\ i = 1, \dots, k \end{matrix},$$

that is  $D_1 = X_\eta$ , and  $D_2$  is  $n \times q$  and consists of the following derivatives

$$\frac{\partial h(z_t; \beta, \eta)}{\partial \eta_j} = \frac{\partial x_0(z_t, \eta)}{\partial \eta_j} + \beta_1 \frac{\partial x_1(z_t, \eta)}{\partial \eta_j} + \dots + \beta_k \frac{\partial x_k(z_t, \eta)}{\partial \eta_j}$$

$$(t = 1, \dots, n; j = 1, \dots, q);$$

$D_2$  can be presented as  $D_2 = \begin{bmatrix} \dot{w}_1 + \dot{X}_1 \beta & \dots & \dot{w}_q + \dot{X}_q \beta \end{bmatrix}$ , where  $\dot{w}_j$  is a  $n \times 1$  vec-

tor consisting of  $\frac{\partial x_0(z_t, \eta)}{\partial \eta_j}$  ( $t = 1, \dots, n$ ) and  $\dot{X}_j$  is a  $n \times k$  matrix consisting of  $\frac{\partial x_i(z_t, \eta)}{\partial \eta_j}$  ( $t = 1, \dots, n; i = 1, \dots, k$ ). Thus in the case of the partly linear model we obtain

$$p_J(\theta) = p_J(\beta, \eta) \propto \begin{vmatrix} X'_\eta X_\eta & X'_\eta D_2 \\ D_2' X_\eta & D_2' D_2 \end{vmatrix}^{\frac{1}{2}}$$

and Jeffreys' (or Bernardo's reference) prior may depend on  $\beta$  since  $D_2$  depends on  $\beta$  for nonzero  $\dot{X}_1, \dots, \dot{X}_q$ . This leads to the following conclusion: for the special subclass of partly linear models where  $x_1, \dots, x_k$  do not depend on  $\eta$ , that is for

$$h(z_t; \beta, \eta) = x_0(z_t, \eta) + \beta_1 x_1(z_t) + \dots + \beta_k x_k(z_t), \quad (4.1)$$

Jeffreys' (or reference) prior takes the form<sup>3)</sup>

$$p_J(\beta, \eta, \omega) \propto \omega^{-1} g_J(\eta), \quad (4.2)$$

where

$$g_J(\eta) \propto \begin{vmatrix} X'_\eta X_\eta & X'_\eta \dot{W} \\ \dot{W}' X_\eta & \dot{W}' \dot{W} \end{vmatrix}^{\frac{1}{2}}, \quad \dot{W} = [\dot{w}_1 \dots \dot{w}_q],$$

for other cases Jeffreys' prior usually depends on  $\beta$ .

It should be noticed, however, that there are other models (functional forms) which lead to reference priors not as convenient as (4.2) but still

---

3) Note that  $g_J(\eta)$  is not a marginal prior, but a way of notation indicating that  $p_J(\beta, \eta)$  does not depend on  $\beta$ .

allowing for analytical integrations with respect to  $\beta$ . Let us consider the following functional form:

$$h(z_t; \beta, \eta) = \beta_1 x_1(z_t, \eta) + \beta_2 x_2(z_t) + \dots + \beta_k x_k(z_t), \quad (4.3)$$

where  $x_0(z_t, \eta) \equiv 0$  and only one  $x_i$  (say,  $x_1$ ) depends on  $\eta$ . In this case only first columns of  $\dot{X}_1, \dots, \dot{X}_q$  are nonzero, so  $D_2$  can be presented as  $D_2 = \beta_1 G$ , where  $G$  consists of those nonzero columns of  $\dot{X}_1, \dots, \dot{X}_q$ . Now Jeffreys' prior takes the form

$$p_J(\beta, \eta, \omega) \propto \omega^{-1} |\beta_1|^q g_J(\eta), \quad (4.4)$$

$$g_J(\eta) \propto \begin{vmatrix} X'_\eta X_\eta & X'_\eta G \\ G' X_\eta & G' G \end{vmatrix}^{1/2},$$

and the corresponding joint posterior PDF takes the form

$$p_J(\beta, \eta, \omega | y, Z) \propto g_J(\eta) s_\eta^{-\frac{n-k}{2}} |X'_\eta X_\eta|^{-\frac{1}{2}} |\beta_1|^q p_N^k \left[ \beta | b_\eta, \frac{1}{\omega} (X'_\eta X_\eta)^{-1} \right] \times \\ \times p_Y \left[ \omega | \frac{n-k}{2}, \frac{s_\eta}{2} \right].$$

Now it is obvious that

$$p_J(\beta, \eta | y, Z) \propto g_J(\eta) s_\eta^{-\frac{n-k}{2}} |X'_\eta X_\eta|^{-\frac{1}{2}} |\beta_1|^q p_S^k \left[ \beta | n-k, b_\eta, \frac{n-k}{s_\eta} X'_\eta X_\eta \right]$$

and that posterior analysis involves higher-order moments of  $t$  distribution; see Osiewalski (1987) and Osiewalski and Goryl (1988) for detailed derivations (as well as examples) in some specific cases with  $k = 1$  and  $q \leq 2$ .

Obviously, even in the relatively simple situations described above, the form of  $p_J(\eta)$  may be so complicated that we do not expect

Jeffreys' prior to become widely used. The practice of using uniform priors for all structural parameters<sup>4)</sup>, like in H. Tsurumi and Y. Tsurumi (1976), could be justified by Savage's "precise measurement" (or "stable estimation") principle - see DeGroot (1970) - but only when the number of observations is "reasonably large"; now the problem of the form of the prior is replaced by the question whether our sample is large enough to rely on inferences corresponding to the uniform prior. It should be stressed that the choice of some simple prior of the form  $p_1(\beta, \eta, \omega)$  as a "noninformative" one may have only practical (convenience) and intuitive justifications.

---

4) When assuming such a prior for one specific parameterization of a given nonlinear model one should be aware of the consequences of reparameterization. For example, if  $\epsilon$  ( $\epsilon > 0$ ) is the elasticity-of-substitution parameter in the CES function (see Subsection 6.2), then the notationally most convenient (and usually used) parameterization is in terms of  $\rho = (1 - \epsilon)/\epsilon = \epsilon^{-1} - 1$ . If we assume, like in Tsurumi and Tsurumi (1976),  $p(\rho) = \text{const}$  as a "noninformative" prior, we obtain a rather strange-looking form  $p(\epsilon) \propto \epsilon^{-2}$ , which gives an infinite prior probability that  $\epsilon < a$ , but a finite prior probability that  $\epsilon > a$  ( $a > 0$ , say:  $a = 1$ ). Parameterizing directly in terms of  $\epsilon$  and assuming  $p(\epsilon) \propto \epsilon^{-1}$ , like in Sankar (1970), gives much more reasonable expression of prior ignorance; it is equivalent to  $p(\rho) \propto (1 + \rho)^{-1}$ , which is nonuniform in  $\rho$ . This difference in "noninformative" priors may lead to different posterior results in small samples.

## 5. Posterior and predictive PDF's corresponding to priors in the form of finite mixtures

### 5.1. Advantages of finite-mixture priors

In this section we allow for expressing prior beliefs about  $\beta$  in such a way that still enables analytical integrations of posterior PDF with respect to  $\beta$ . Of course, normal or t priors of  $\beta$  are the most convenient informative priors from the analytical and numerical point of view. On the other hand, they can prove too restrictive in practice because of their symmetry and unimodality. In order to obtain more flexible (but still convenient) classes of priors, finite mixtures of normal or t distributions seem worth considering.<sup>5)</sup> As simple examples show, finite mixtures of univariate normal distributions can produce priors of quite different shapes: multimodal, asymmetric, platykurtic - even if the number of components of the mixture is very small; some preliminary work on expressing prior beliefs in the form of such mixtures was done by Bijak (1987), but elicitation problems are outside the scope of this paper and need separate considerations. Here we are interested in the form and tractability of posterior and predictive PDF's corresponding to finite-mixture priors. Let us consider the general case first;  $l(\delta|\text{data})$  denotes the likelihood function, where  $\delta \in \Delta$  is a vector of parameters, and  $p(\tilde{y}|\text{data}, \delta)$  denotes the conditional PDF of future observations ( $\tilde{y}$ ) given data and parameters. If  $p_g(\delta)$  is the prior density then, obviously, the posterior and predictive densities are given by

$$p_g(\delta|\text{data}) = K_g^{-1} p_g(\delta) l(\delta|\text{data}),$$

$$p_g(\tilde{y}|\text{data}) = \int_{\Delta} p(\tilde{y}|\text{data}, \delta) p_g(\delta|\text{data}) d\delta,$$

where  $K_g = \int_{\Delta} p_g(\delta) l(\delta|\text{data}) d\delta$ .

---

5) The idea of taking mixtures as priors comes from Dalal and Hall (1983).

But when the prior is represented by a finite mixture of such  $p_g(\delta)$  for  $g = 1, \dots, G$  (with weights  $c_g$  which are positive and sum up to 1), that is when

$$p(\delta) = \sum_{g=1}^G c_g p_g(\delta),$$

then

$$\begin{aligned} p(\delta|\text{data}) &= \frac{p(\delta) l(\delta|\text{data})}{\int_{\Delta} p(\delta) l(\delta|\text{data}) d\delta} = \frac{\sum_g c_g p_g(\delta) l(\delta|\text{data})}{\sum_g c_g K_g} = \\ &= \sum_g \bar{c}_g p_g(\delta|\text{data}), \end{aligned}$$

where

$$\bar{c}_g = c_g K_g / \sum_g c_g K_g,$$

and

$$\begin{aligned} p(\tilde{y}|\text{data}) &= \int_{\Delta} p(\tilde{y}|\text{data}, \delta) p(\delta|\text{data}) = \\ &= \sum_g \bar{c}_g p_g(\tilde{y}|\text{data}), \end{aligned}$$

thus the "overall" posterior and predictive PDF's are in the form of finite mixtures of "individual" posterior and predictive PDF's. If, for every  $g$ , there exist posterior and predictive moments about 0, then the corresponding "overall" moments about 0 are simply weighted averages of "individual" ones; the same property holds for marginal densities. And, what is most important for our purposes, if all "individual" posterior densities are analytically tractable (with respect to some  $\delta_i$ ) then the "overall" posterior is tractable (with respect to this  $\delta_i$ ). In the case considered in the paper we insist on taking advantages of partial linearity of the model, thus we insist on analytical integrability of the posterior PDF with respect to  $\beta$ . This is the reason of our special interest in

mixtures of normal or  $t$  distributions of  $\beta$ . Assuming mixtures, we can proceed in two equivalent ways: to sum up "individual" results (weighted appropriately) or to derive directly "overall" results (which in the case of  $G = 1$  are the same as "individual" ones). We adopt the second approach in the rest of this section.

Finite-mixture priors could be interpreted as representing prior information coming from several different (jointly exhaustive and mutually exclusive) sources. But generally mixtures can be treated merely as an useful approximation of some preassigned shape of prior density. Such an attitude was adopted by Dalal and Hall (1983) and is adopted here as well.

## 5.2. Mixtures of normal distributions

We assume the following conditional prior density<sup>6)</sup> of  $\beta$  given  $\eta$ :

$$p_2(\beta|\eta) = \sum_{g=1}^G c_g p_N^k\left[\beta|a_g, A_g^{-1}\right],$$

where  $G \geq 1$ ,  $c_g > 0$ ,  $\sum_g c_g = 1$ ,  $a_g \in R^k$  and  $A_g$  are PDS of order  $k$ .

The joint prior density for all parameters takes the form

$$p_2(\beta, \eta, \omega) = p_2(\beta|\eta) p(\eta) p(\omega) \propto$$

$$\propto p(\eta) \omega^{\frac{e}{2}-1} \exp\left(-\frac{f}{2} \cdot \omega\right) \sum_g c_g |A_g|^{-\frac{1}{2}} \exp\left[-\frac{1}{2} (\beta - a_g)' A_g (\beta - a_g)\right].$$

For this prior and the likelihood given by (3.2), Bayes' theorem leads to the following joint posterior PDF:

---

6) Our analysis here, as well as in Subsection 5.3, allows for prior dependence between  $\beta$  and  $\eta$ ; parameters of  $p_i(\beta|\eta)$ ,  $i = 2, 3$ , can be some functions of  $\eta$ . Obviously, the special case:  $p_i(\beta|\eta) = p_i(\beta)$  seems the most convenient one in practice.

$$\begin{aligned}
p_2(\beta, \eta, \omega | y, Z) &\propto p_2(\beta, \eta, \omega) p(y | Z, \beta, \eta, \omega) \propto \\
&\propto p(\eta) \omega^{\frac{e+n}{2}-1} \exp\left[-\frac{f+s}{2}\eta, \omega\right] \cdot \sum_g c_g |A_g|^{\frac{1}{2}} \exp\left\{-\frac{1}{2}[(\beta - a_g)' A_g (\beta - a_g) + \right. \\
&\quad \left. + \omega(\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta)]\right\}.
\end{aligned}$$

For  $\bar{A}_g = A_g + \omega X_\eta' X_\eta$  and  $\bar{a}_g = \bar{A}_g^{-1}(A_g a_g + \omega X_\eta' X_\eta b_\eta)$  we have

$$\begin{aligned}
(\beta - a_g)' A_g (\beta - a_g) + \omega(\beta - b_\eta)' X_\eta' X_\eta (\beta - b_\eta) &= \\
= (\beta - \bar{a}_g)' \bar{A}_g (\beta - \bar{a}_g) + d_g,
\end{aligned}$$

where

$$d_g = a_g' A_g a_g + \omega b_\eta' X_\eta' X_\eta b_\eta - \bar{a}_g' \bar{A}_g \bar{a}_g; \quad d_g \geq 0.$$

Now the joint posterior PDF can be written as

$$\begin{aligned}
p_2(\beta, \eta, \omega | y, Z) &\propto \\
&\propto p(\eta) \omega^{\frac{e+n}{2}-1} \exp\left[-\frac{f+s}{2}\eta, \omega\right] \sum_g c_g |A_g \cdot \bar{A}_g^{-1}|^{\frac{1}{2}} \exp\left[-\frac{d_g}{2}\right] p_N^k(\beta | \bar{a}_g, \bar{A}_g^{-1}).
\end{aligned}$$

Let us denote

$$\begin{aligned}
C_g &= c_g |A_g \cdot \bar{A}_g^{-1}|^{\frac{1}{2}} \exp\left[-\frac{d_g}{2}\right], \\
C &= \sum_g C_g, \quad \bar{C}_g = C^{-1} C_g;
\end{aligned}$$

now

$$p_2(\beta, \eta, \omega, | y, Z) \propto p(\eta) \omega^{\frac{e+n}{2}-1} \exp\left[-\frac{f+s}{2}\eta, \omega\right] C \sum_g \bar{C}_g p_N^k(\beta | \bar{a}_g, \bar{A}_g^{-1}).$$

Since  $\bar{c}_g > 0$  and  $\sum_g \bar{c}_g = 1$ , then

$$\int_{R^k} \sum_g \bar{c}_g p_N^k[\beta | \bar{a}_g, \bar{A}_g^{-1}] d\beta = \sum_g \bar{c}_g \int_{R^k} p_N^k[\beta | \bar{a}_g, \bar{A}_g^{-1}] d\beta = 1,$$

$$p_2(\eta, \omega | y, Z) = \int_{R^k} p_2(\beta, \eta, \omega | y, Z) d\beta \propto$$

$$\propto p(\eta) \omega^{\frac{e+n}{2}-1} \exp\left[-\frac{f+s}{2} \eta \cdot \omega\right] C,$$

$$\text{and } p_2(\beta | y, Z, \eta, \omega) = \sum_g \bar{c}_g p_N^k[\beta | \bar{a}_g, \bar{A}_g^{-1}].$$

The joint posterior PDF is now expressed as a product of the marginal posterior PDF of  $(\eta, \omega)$ :

$$p_2(\beta, \eta, \omega | y, Z) = p_2(\eta, \omega | y, Z) p_2(\beta | y, Z, \eta, \omega),$$

the latter density being the mixture of  $k$ -dimensional normal PDF's. Inferences about  $\eta$  (and  $\omega$ , if necessary) will be based on the marginal posterior of  $(\eta, \omega)$ ; in order to calculate its normalizing constant, moments and univariate marginal densities numerical integrations will be required. For inferences about  $\beta$ , its marginal posterior is appropriate. The marginal posterior PDF of  $\beta$  can be expressed as the following integral

$$p_2(\beta | y, Z) = \int_H \int_0^\infty p_2(\eta, \omega | y, Z) p_2(\beta | y, Z, \eta, \omega) d\omega d\eta.$$

Since conditional moments and univariate densities are given by known analytical formulae then marginal moments and univariate densities can be calculated as follows:

$$E_2(\beta | y, Z) = \int_H \int_0^\infty p_2(\eta, \omega | y, Z) \sum_g \bar{c}_g \bar{a}_g d\omega d\eta,$$

$$E_2(\beta \beta' | y, Z) = \int_H \int_0^\infty p_2(\eta, \omega | y, Z) \sum_g \bar{c}_g \left[ \bar{A}_g^{-1} + \bar{a}_g \cdot \bar{a}_g' \right] d\omega d\eta,$$

$$p_2(\beta_i | y, Z) = \int_H \int_0^\infty p_2(\eta, \omega | y, Z) \sum_g \bar{c}_g p_N^1\left(\beta_i | \left[\bar{a}_g\right]_i, \left[\bar{A}_g^{-1}\right]_{ii}\right) d\omega d\eta;$$

similarly for mixed moments of  $\beta$  and  $\eta$ :

$$E_2(\eta, \beta' | y, Z) = \int_H \int_0^\infty p_2(\eta, \omega | y, Z) \cdot \eta \cdot \sum_g \bar{c}_g \bar{a}_g' d\omega d\eta.$$

In order to derive the predictive PDF  $p_2(\tilde{y} | y, Z, \tilde{Z})$  according to (2.2), let us write is as

$$\begin{aligned} p_2(\tilde{y} | y, Z, \tilde{Z}) &= \int_H \int_0^\infty \int_{R^k} p(\tilde{y} | \tilde{Z}, \beta, \eta, \omega) p_2(\beta | y, Z, \eta, \omega) d\beta \times \\ &\times p_2(\eta, \omega | y, Z) d\omega d\eta. \end{aligned}$$

By analytical integration with respect to  $\beta$  - on the basis of (1.1) - we obtain

$$\begin{aligned} p_2(\tilde{y} | y, Z, \tilde{Z}) &= \int_H \int_0^\infty p_2(\eta, \omega | y, Z) \sum_g \bar{c}_g p_N^m\left[\tilde{y} | \tilde{w}_\eta + \tilde{X}_\eta \bar{a}_g, \right. \\ &\quad \left. \tilde{X}_\eta \bar{A}_g^{-1} \tilde{X}_\eta' + \frac{1}{\omega} I_m\right] d\omega d\eta, \end{aligned}$$

and it is easy to deduce the formulae for moments and univariate densities of the predictive distribution.

In the case of the prior considered here, Bayesian estimation and prediction requires  $(q+1)$ -dimensional numerical integrations, irrespective of  $k$ . For practical reasons, only mixtures of a small number of terms are attractive. Let us note that there is no special advantage of the type of prior assumed here over any other type of informative prior if  $k = 1$  ( $\beta$  is a scalar parameter). For any  $p(\beta, \eta)$ ,  $\beta \in R^k$  and  $\eta \in R^q$ , we can always integrate  $\omega$  out analytically and then the dimension of integrals to be calculated is  $K = k + q$  (see Section 2); in the case of  $p_2(\beta, \eta)$ , considered here, we integrate  $\beta$  out analytically and then  $(q+1)$ -dimensional numerical integration (over  $\eta$  and  $\omega$ ) remains. When  $k = 1$ , both approaches lead to different, but  $(q+1)$ -dimensional integrals.

### 5.3. Mixtures of t distributions

Finite mixtures of normal distributions are quite flexible, except for their tail behaviour which is essentially the same as in the case of one normal distribution. In order to obtain fatter tails of the prior distribution of  $\beta$  given  $\eta$ , a finite mixture of  $k$ -variate Student  $t$  distributions can be applied. This mixture can formally be treated as a marginal distribution from the following mixture of normal-gamma distributions of  $\beta$  and an additional parameter  $\tau > 0$ :

$$p_3(\beta, \tau | \eta) = \sum_{g=1}^G c_g p_N^k \left[ \beta | a_g, (\tau A_g)^{-1} \right] p_\gamma \left[ \tau | \frac{1}{2}, \frac{v}{2} \right], \quad (5.1)$$

since the integration with respect to  $\tau$  leads to

$$p_3(\beta | \eta) = \int_0^\infty p_3(\beta, \tau | \eta) d\tau = \sum_{g=1}^G c_g p_s^k \left[ \beta | l_g, a_g, \frac{1}{v_g} A_g \right].$$

We adopt (5.1) as a starting point for the derivation of posterior and predictive results corresponding to the prior  $p_3(\beta | \eta)$ .<sup>7)</sup> The joint prior density of  $\beta$ ,  $\eta$ ,  $\omega$  and the additional parameter  $\tau$  is as follows:

$$p_3(\beta, \eta, \omega, \tau) \propto p(\eta) \omega^{\frac{e}{2}-1} \exp\left(-\frac{f}{2} \cdot \omega\right) \sum_g c_g p_N^k \left[ \beta | a_g, (\tau A_g)^{-1} \right] \times \\ \times p_\gamma \left[ \tau | \frac{1}{2}, \frac{v}{2} \right].$$

For this prior and the likelihood given by (3.2) one obtains the following joint posterior PDF:

---

7) Multiplying  $p_3(\beta, \eta, \omega) = p_3(\beta | \eta) p(\eta) p(\omega)$  by the likelihood (3.2) and integrating  $\omega$  out, we would obtain a finite mixture of double- $t$  (2-0 poly- $t$ ) densities as a conditional posterior PDF of  $\beta$  given  $\eta$  (and some marginal posterior PDF of  $\eta$ ). Thus (5.1) enables us to perform analytical integrations with respect to  $\beta$  in the same way as in Dickey (1968).

$$\begin{aligned}
p_3(\beta, \eta, \omega, \tau | y, Z) &\propto p_3(\beta, \eta, \omega, \tau) p(y | Z, \beta, \eta, \omega) \propto p(\eta) \omega^{\frac{e+n}{2}-1} \times \\
&\times \exp\left[-\frac{f+s}{2}\eta \cdot \omega\right] \sum_g c_g p_{\mathcal{Y}}\left(\tau \middle| \frac{1}{2}\bar{g}, \frac{v}{2}\bar{g}\right) \tau^{\frac{k}{2}} |A_g|^{\frac{1}{2}} \exp\left\{-\frac{\tau}{2}[(\beta - a_g)' A_g (\beta - a_g) + \right. \\
&\left. + \frac{\omega}{\tau} (\beta - b_g)' X'_{\eta} X_{\eta} (\beta - b_g)]\right\}.
\end{aligned}$$

Let us denote  $\lambda = \frac{\omega}{\tau}$  and define matrices  $\bar{A}_g$ , vectors  $\bar{a}_g$  and scalars  $d_g$  similarly as in the previous subsection (merely replacing  $\omega$  by  $\lambda$ ):

$$\begin{aligned}
\bar{A}_g &= A_g + \lambda X'_{\eta} X_{\eta}, \quad \bar{a}_g = \bar{A}_g^{-1} (A_g a_g + \lambda X'_{\eta} X_{\eta} b_g), \\
d_g &= a_g' A_g a_g + \lambda b_g' X'_{\eta} X_{\eta} b_g - \bar{a}_g' \bar{A}_g \bar{a}_g \quad (\text{always } d_g \geq 0).
\end{aligned}$$

Now we can present the joint posterior PDF in the following form:

$$\begin{aligned}
p_3(\beta, \eta, \omega, \tau | y, Z) &\propto \\
&\propto p(\eta) \omega^{\frac{e+n}{2}-1} \exp\left[-\frac{f+s}{2}\eta \cdot \omega\right] \sum_g c_g |A_g \bar{A}_g^{-1}|^{\frac{1}{2}} p_{\mathcal{Y}}\left(\tau \middle| \frac{1}{2}\bar{g}, \frac{v}{2}\bar{g}\right) \times \\
&\times \exp\left[-\frac{\tau}{2} d_g\right] p_N^k\left[\beta | \bar{a}_g, (\tau \bar{A}_g)^{-1}\right].
\end{aligned}$$

After the transformation:  $(\omega, \tau) \rightarrow (\lambda, \tau)$ , with the Jacobian equal to  $\tau$ , one obtains

$$\begin{aligned}
p_3(\beta, \eta, \lambda, \tau | y, Z) &\propto p(\eta) \lambda^{\frac{e+n}{2}-1} \tau^{\frac{e+n}{2}} \exp\left[-\frac{f+s}{2}\eta \lambda \tau\right] \times \\
&\times \sum_g c_g |A_g \bar{A}_g^{-1}|^{\frac{1}{2}} p_{\mathcal{Y}}\left(\tau \middle| \frac{1}{2}\bar{g}, \frac{v}{2}\bar{g}\right) \exp\left[-\frac{\tau}{2} d_g\right] p_N^k\left[\beta | \bar{a}_g, (\tau \bar{A}_g)^{-1}\right].
\end{aligned}$$

Defining

$$\bar{l}_g = l_g + e + n, \quad \bar{v}_g = v_g + d_g + (f + s_{\eta})\lambda,$$

$$C_g = c_g \left| A_g \bar{A}_g^{-1} \right|^{\frac{1}{2}} \left[ \Gamma \left( \frac{1}{2} \right) \right]^{-1} \Gamma \left( \frac{1}{2} \right) v_g^{\frac{1}{2}} \bar{v}_g^{-\frac{1}{2}},$$

$$C = C(\eta, \lambda) = \sum_g C_g, \quad \bar{C}_g = C^{-1} C_g$$

one can write

$$p_3(\beta, \eta, \lambda, \tau | y, Z) \propto p(\eta) \lambda^{\frac{e+n}{2}-1} \sum_g C_g p_Y \left( \tau \left| \frac{1}{2}, \frac{\bar{v}}{2} \right. \right) p_N^k \left( \beta | \bar{a}_g, (\tau \bar{A}_g)^{-1} \right)$$

or

$$p_3(\beta, \eta, \lambda, \tau | y, Z) = p_3(\eta, \lambda | y, Z) p_3(\beta, \tau | y, Z, \eta, \lambda),$$

$$p_3(\eta, \lambda | y, Z) \propto p(\eta) \lambda^{\frac{e+n}{2}-1} C(\eta, \lambda),$$

$$p_3(\beta, \tau | y, Z, \eta, \lambda) = \sum_g \bar{C}_g p_Y \left( \tau \left| \frac{1}{2}, \frac{\bar{v}}{2} \right. \right) p_N^k \left( \beta | \bar{a}_g, (\tau \bar{A}_g)^{-1} \right).$$

Since integrations with respect to  $\beta$  and  $\tau$  can be performed analytically, the above-presented forms of the joint posterior PDF seem relatively convenient. For estimation purposes,  $\tau$  should be integrated out in order to obtain

$$p_3(\beta | y, Z, \eta, \lambda) = \int_0^\infty p_3(\beta, \tau | y, Z, \eta, \lambda) d\tau = \sum_g \bar{C}_g p_s^k \left( \beta | \bar{l}_g, \bar{a}_g, \frac{1}{\bar{v}} \bar{A}_g \right)$$

and then

$$p_3(\beta, \eta, \lambda | y, Z) = p_3(\beta | y, Z, \eta, \lambda) p_3(\eta, \lambda | y, Z).$$

Calculation of the normalizing constant of  $p_3(\eta, \lambda | y, Z)$  as well as inferences about  $\beta$  and  $\eta$  (in terms of posterior first- and second-order moments and univariate marginal densities) require numerical integrations in the

$(\eta, \lambda)$ -space; for  $\beta$ , the appropriate formulae can be easily derived on the basis of known properties of t distributions.

In order to obtain and analyse the predictive distribution corresponding to t-mixture prior one can rewrite  $p(\tilde{y}|\tilde{Z}, \beta, \eta, \omega)$  in terms of  $\lambda$  and  $\tau$  (instead of  $\omega$ ):

$$p(\tilde{y}|\tilde{Z}, \beta, \eta, \lambda, \tau) = p(\tilde{y}|\tilde{Z}, \beta, \eta, \omega = \lambda\tau) = p_N^m\left[\tilde{y}|\tilde{w}_\eta + \tilde{X}_\eta\beta, \frac{1}{\lambda\tau} I_m\right]$$

and then derive analytically, according to (1.1) and (1.3),

$$\begin{aligned} p_3(\tilde{y}|y, Z, \tilde{Z}, \eta, \lambda) &= \int_0^\infty \int_{R^k} p(\tilde{y}|\tilde{Z}, \beta, \eta, \lambda, \tau) p_3(\beta, \tau|y, Z, \eta, \lambda) d\beta d\tau = \\ &= \sum_g \bar{c}_g \int_0^\infty p_{\mathcal{Y}}\left[\tau \middle| \frac{\bar{I}_g}{2}, \frac{\bar{v}_g}{2}\right] \int_{R^k} p_N^m\left[\tilde{y}|\tilde{w}_\eta + \tilde{X}_\eta\beta, \frac{1}{\lambda\tau} I_m\right] p_N^k\left[\beta|\bar{a}_g, \right. \\ &\quad \left. (\tau\bar{A}_g)^{-1}\right] d\beta d\tau = \sum_g \bar{c}_g p_S^m\left[\tilde{y}|\bar{I}_g, \tilde{w}_\eta + \tilde{X}_\eta\bar{a}_g, \frac{\bar{I}_g}{\bar{v}_g} \left[\tilde{X}_\eta\bar{A}_g^{-1}\tilde{X}_\eta' + \frac{1}{\lambda} I_m\right]^{-1}\right]. \end{aligned}$$

Now it is obvious that the analysis of the predictive PDF

$$p_3(\tilde{y}|y, Z, \tilde{Z}) = \int_H \int_0^\infty p_3(\tilde{y}|y, Z, \tilde{Z}, \eta, \lambda) p_3(\eta, \lambda|y, Z) d\lambda d\eta$$

exploits known properties of t distributions and requires  $(q+1)$ -dimensional numerical integrations, irrespective of  $k$  and  $m$  (the dimensions of  $\beta$  and  $\tilde{y}$ , respectively).

## 6. Concluding remarks and comments on applications

### 6.1. Discussion of the results

Let us treat the model under consideration, that is

$$y_t = x_0(z_t, \eta) + \beta_1 x_1(z_t, \eta) + \dots + \beta_k x_k(z_t, \eta) + u_t,$$

$$u_t \sim \text{iin}(0, \sigma^2), \quad \eta \in H \subset \mathbb{R}^q, \quad \beta = (\beta_1, \dots, \beta_k)' \in \mathbb{R}^k,$$

not as a special case of the nonlinear regression, but as an useful general representation of linear and nonlinear regression models. In order to achieve this generality, we allow for  $q = 0$  ( $\eta$  does not exist) or  $k = 0$  ( $\beta$  does not exist), but with obvious restriction that  $k + q \geq 1$  (there exists at least one unknown parameter). The following situations are possible:

- (i)  $q = 0$ ; the model is linear in all its parameters. From Subsections 4.1, 5.2 and 5.3, conditional posterior and predictive results (given  $\eta$ ) remain valid; of course part of them (Subsection 4.1) are standard and well-known, but the use of finite-mixture priors seems new even in the linear context.
- (ii)  $k = 0$ ; there is no possibility to represent a given nonlinear model in the "partly linear" form. We have a "completely nonlinear" model:  $\theta = \eta$ ,  $h(z_t, \theta) = x_0(z_t, \eta)$ , and we are back in Section 2 with Bayesian estimation and prediction based on (2.3) and (2.4).
- (iii)  $k > 0$  and  $q > 0$ ; we have the partly linear regression model considered in Sections 3-5.

The main conclusion is that exact Bayesian analysis is possible if  $q$  is small, irrespective of  $k$ ; of course the meaning of "small" is not precise and depends on computer facilities.

If, additionally,  $k = 0$  or  $k = 1$ , then at most  $(q+1)$ -dimensional numerical integrations are required irrespective of the choice of the prior density

$p(\beta, \eta)$ . However, if  $k > 1$ , then the classes of prior densities adopted in the paper seem specially attractive, since they are flexible and always lead to at most  $(q+1)$ -dimensional numerical integration.

If  $q$  is large (too large to perform integrations numerically) then integration by Monte Carlo methods or approximations are required. But - if only  $k > 0$  - there are still some advantages of the proposed classes of priors, since we have exact analytical posterior and predictive results conditionally on  $\eta$  or  $(\eta, w)$  or  $(\eta, \lambda)$ .

## 6.2. Applications to CES production functions

Let us point at some new possibilities in this case, where the model under consideration takes the form

$$V_t = \left[ \delta C_t^{(\epsilon-1)/\epsilon} + (1-\delta) L_t^{(\epsilon-1)/\epsilon} \right]^{\nu\epsilon/(\epsilon-1)} \exp(\beta_2 x_{t2} + \dots + \beta_k x_{tk} + u_t);$$

$x_{t2}, \dots, x_{tk}$  can be dummy, time or other variables. Taking the logarithms of both sides, we obtain the partly linear regression model

$$y_t = \beta_1 x_{t1}(\eta) + \beta_2 x_{t2} + \dots + \beta_k x_{tk} + u_t, \quad (6.1)$$

where

$$y_t = \ln V_t, \quad \beta_1 = \nu, \quad \eta = (\delta \epsilon)' \in (0, 1) \times (0, +\infty),$$

$$x_{t1}(\eta) = \begin{cases} \frac{\epsilon}{\epsilon-1} \ln \left[ \delta C_t^{(\epsilon-1)/\epsilon} + (1-\delta) L_t^{(\epsilon-1)/\epsilon} \right], & \epsilon \neq 1, \\ \delta \ln C_t + (1-\delta) \ln L_t, & \epsilon = 1; \end{cases}$$

the Cobb-Douglas case ( $\epsilon = 1$ ) is included in order to preserve continuity with respect to  $\epsilon$ , the elasticity-of-substitution parameter. First, it is possible to incorporate prior knowledge in the forms proposed in Section 5 and trivariate numerical integration is sufficient to obtain exact

Bayesian results; previous Bayesian analyses of CES functions used only simple priors, uniform in  $\beta$ .

Second, (6.1) is in the form (4.3), so Jeffreys' (reference) prior is

$$p_J(\beta, \eta, \sigma) \propto \sigma^{-1} \beta_1^2 g_J(\eta) = \sigma^{-1} \nu^2 g_J(\eta),$$

where  $g_J(\eta)$  is in the form (4.4). Now it is possible to make comparisons between results corresponding to Jeffreys' prior and to simpler (intuitively noninformative) prior used in the literature.

### 6.3. Logistic curves

The approach developed in the paper enables the exact Bayesian analysis of the following generalizations of the logistic growth curve:

$$Y_t = \frac{\exp(\beta_1 x_{t1} + \dots + \beta_k x_{tk})}{1 + \eta_2 \exp(-\eta_1 \cdot v_t)} \exp(u_t), \quad (6.2)$$

or

$$Y_t = \beta_0 + \frac{\beta_1 x_{t1} + \dots + \beta_k x_{tk}}{1 + \eta_2 \exp(-\eta_1 \cdot v_t)} + u_t, \quad (6.3)$$

where  $\eta_1, \eta_2 > 0$ ,  $u_t \sim \text{iin}(0, \sigma^2)$  and  $x_{t1}, \dots, x_{tk}, v_t$  are some explanatory variables. The simplest special cases of (6.2) and (6.3), that is

$$Y_t = \frac{\exp(\beta_1)}{1 + \eta_2 \exp(-\eta_1 \cdot t)} \exp(u_t), \quad (6.4)$$

$$Y_t = \frac{\beta_1}{1 + \eta_2 \exp(-\eta_1 \cdot t)} + u_t, \quad (6.5)$$

were analyzed under Jeffreys' prior by Osiewalski and Goryl (1986, 1988). For (6.4) and several sets of data, two other priors (intuitively "noninformative") were also adopted and led to almost the same posteriors as Jeffreys' prior did; marginal posterior densities were always unimodal, almost symmetric or slightly asymmetric and exact Bayesian results were close to ML (that is, to Bayesian approximate large-sample) results. On

the other hand, another example - with (6.5) and Jeffreys' prior - revealed large discrepancies between the exact posterior mean and standard deviation of  $\eta_2$  and their approximate (ML) counterparts. Since the marginal posterior density of  $\eta_2$  had a lognormal-like shape, it was easy to propose a "better" parameterization of (6.5), namely in terms of  $\eta_0 = \ln \eta_2$ , which led to closer exact and approximate (ML) results. For a Bayesian, if only an exact analysis is possible - and it is possible for such models as (6.2) and (6.3) - then there is no fundamental need to seek such a "better" parameterization, even when it is easy to find by inspection of marginal posterior densities. This contrasts with the classical approach to nonlinear regression models, where a "good" parameterization is crucial to rely on ML results in a small sample, and it proves difficult to find such a parameterization; see Ratkowsky (1983), where the classical estimation of logistic functions and many other nonlinear models is presented.

#### 6.4. A generalization to nonscalar error covariance matrices

Let us consider the case when the disturbances of our partly linear model have a nonscalar covariance matrix.

We assume the following model:

$$\begin{bmatrix} y \\ \tilde{y} \end{bmatrix} = \begin{bmatrix} w_\eta \\ \tilde{w}_\eta \end{bmatrix} + \begin{bmatrix} x_\eta \\ \tilde{x}_\eta \end{bmatrix} \beta + \begin{bmatrix} u \\ \tilde{u} \end{bmatrix},$$

$$\begin{bmatrix} u \\ \tilde{u} \end{bmatrix} \sim N \left( 0, \frac{1}{\omega} \begin{bmatrix} V_\varphi & \bar{V}_\varphi \\ \bar{V}_\varphi' & \tilde{V}_\varphi \end{bmatrix} \right),$$

where  $\varphi \in \Phi$  is an additional unknown parameter (vector) and  $V_\varphi$ ,  $\bar{V}_\varphi$ ,  $\tilde{V}_\varphi$  are known functions of  $\varphi$ . For example, when the disturbances are described by the normal stationary AR(1) process

$$u_t = \varphi u_{t-1} + \varepsilon_t, \quad \varepsilon_t \sim \text{iid} N(0, \omega^{-1}),$$

then  $\varphi$  is a scalar parameter,  $\varphi \in (-1, 1)$  and the covariance matrix of  $(u' \tilde{u}')'$  takes the well-known form, namely

$$\text{cov}(u_t, u_{t'}) = \omega^{-1} (1 - \varphi^2)^{-1} \varphi^{|t-t'|},$$

$$t, t' = 1, \dots, n, n+1, \dots, n+m.$$

Now, under a nonscalar covariance matrix,  $\tilde{y}$  and  $y$  may be stochastically dependent (if  $\tilde{V}_\varphi \neq 0$ ) and the following factorization holds

$$p(y, \tilde{y} | Z, \tilde{Z}, \beta, \eta, \omega, \varphi) = p(y | Z, \beta, \eta, \omega, \varphi) p(\tilde{y} | y, Z, \tilde{Z}, \beta, \eta, \omega, \varphi),$$

where

$$\begin{aligned} p(y | Z, \beta, \eta, \omega, \varphi) &= p_N^n(y | w_\eta + X_\eta \beta, \omega^{-1} V_\varphi) = \\ &= (2\pi)^{-\frac{n}{2}} \omega^{\frac{n}{2}} |V_\varphi|^{-\frac{1}{2}} \exp \left\{ -\frac{\omega}{2} \left[ s_{\eta, \varphi} + (\beta - b_{\eta, \varphi})' X_\eta' V_\varphi^{-1} X_\eta (\beta - b_{\eta, \varphi}) \right] \right\}, \end{aligned}$$

$$p(\tilde{y} | y, Z, \tilde{Z}, \beta, \eta, \omega, \varphi) = p_N^m \left[ \tilde{y} | Q_{\eta, \varphi} \beta + \tilde{V}_\varphi' V_\varphi^{-1} (y - w_\eta) + \tilde{w}_\eta, \omega^{-1} S_\varphi \right]$$

and

$$b_{\eta, \varphi} = \left[ X_\eta' V_\varphi^{-1} X_\eta \right]^{-1} X_\eta' V_\varphi^{-1} (y - w_\eta),$$

$$s_{\eta, \varphi} = (y - w_\eta - X_\eta b_{\eta, \varphi})' V_\varphi^{-1} (y - w_\eta - X_\eta b_{\eta, \varphi}),$$

$$Q_{\eta, \varphi} = \tilde{X}_\eta - \tilde{V}_\varphi' V_\varphi^{-1} X_\eta, \quad S_\varphi = \tilde{V}_\varphi - \tilde{V}_\varphi' V_\varphi^{-1} \tilde{V}_\varphi.$$

Assuming the following prior structure

$$p(\beta, \eta, \omega, \varphi) = p(\beta, \eta) p(\omega) p(\varphi), \quad \beta \in R^k, \quad \eta \in H, \quad \varphi \in \Phi, \quad \omega \in R_+,$$

where  $p(\varphi)$  is a marginal prior of  $\varphi$  and, as previously,

$$p(\omega) \propto \omega^{\frac{e}{2}-1} \exp \left[ -\frac{f}{2} \cdot \omega \right],$$

we can proceed in a similar way as in Subsections 4.1, 5.2, 5.3. For example, when the prior is uniform in  $\beta$ , that is when

$$p(\beta, \eta) = p_1(\beta, \eta) \propto g(\eta),$$

we obtain

$$\begin{aligned} p_1(\eta, \varphi | y, Z) &\propto g(\eta) p(\varphi) \left[ |V_\varphi| \cdot |X'_\eta V_\varphi^{-1} X_\eta| \right]^{-\frac{1}{2}} (f + s_{\eta, \varphi})^{-\frac{1}{2}(e+n-k)} \\ p_1(\beta | y, Z, \eta, \varphi) &= p_s^k \left[ \beta | e + n - k, b_{\eta, \varphi}, \frac{e + n - k}{f + s_{\eta, \varphi}} X'_\eta V_\varphi^{-1} X_\eta \right], \\ p_1(\tilde{y} | y, Z, \tilde{Z}) &= \int_{\Phi} \int_H p_1(\eta, \varphi | y, Z) p_s^m \left[ \tilde{y} | e + n - k, Q_{\eta, \varphi} b_{\eta, \varphi} + \right. \\ &\quad \left. + \bar{V}'_\varphi V_\varphi^{-1} (y - w_\eta) + \tilde{w}_\eta, \frac{e + n - k}{f + s_{\eta, \varphi}} \left[ Q_{\eta, \varphi} \left( X'_\eta V_\varphi^{-1} X_\eta \right)^{-1} Q'_{\eta, \varphi} + S_\varphi \right]^{-1} \right] d\eta d\varphi; \end{aligned}$$

numerical integrations with respect to  $\eta$  and  $\varphi$  will usually be needed in order to obtain a normalizing constant, first- and second - order moments and univariate marginal densities of the posterior and predictive distributions. This increase in dimensionality of calculated integrals constitutes the price for unknown  $\varphi$  in the error covariance matrix.<sup>8)</sup> Of course, this exact Bayesian approach is applicable when the matrix  $V_\varphi^{-1}$  has known analytical form (as a function of  $\varphi$ ), since numerical inversions of the  $n \times n$  matrix  $V_\varphi$  for every  $\varphi$  seem impractical.

---

8) See also Richard (1977) where the case of the linear model with autoregressive disturbances is considered. Richard's approach (allowing for nonstationary processes) can be easily generalized to partly linear models.
